

Résumé

Cette carte présente le potentiel de construction et les types de fondations selon les conditions de pergélisol et les pentes de la région de Puvirnituk. Ce village se situe au Nunavik, sur la rive est de la baie d'Hudson, à l'embouchure de la rivière Puvirnituk (60.05° N ; 77.32° O).

Note

Cette carte a été compilée principalement par photo-interprétation et validée avec un nombre limité d'observations de terrain, de sondages et de forages dans le pergélisol. Toute information pouvant en améliorer la précision et éventuellement conduire à la production d'une mise à jour sera appréciée.

Construction potential and foundation design options based on permafrost conditions and slopes

PUVIRNITUQ

Québec, Nunavik
1 : 12 000

- THAW-STABLE GROUND: BEDROCK AND SUPERFICIAL DEPOSITS WITH NO OR LITTLE ICE CONTENT**
- 1a**
- Bedrock sometimes covered with a thin layer of sand, gravel or boulders. Active layer thickness is generally about 4-6 m. Rock joints may contain a small amount of ice.
 - All types of northern foundations. Adaptations to rugged topography are often necessary.
- 1b**
- Thin cover of sand and gravel over bedrock. The thickness of the deposit is generally less than 2 m and the topography is controlled by bedrock. Presence of scattered rock outcrops. The active layer thickness is generally ranging from 1.5 to 2.5 m. Contains pore ice whose volume is generally less than 10%.
 - Deep northern foundations on the underlying bedrock applicable (ex.: pile foundations). Adjustable post and pad foundations also feasible. Buildings with slab-on-grade foundations need elaborated techniques of terrain preparation (ex.: removal or pre-thaw of frozen sediments and consolidation).
- 1c**
- Thick layered sand and gravel deposit. The thickness of the deposit is generally greater than 2 m. The active layer thickness is generally ranging from 1.5 to 2.5 m. Contains pore ice and occasional ice lenses may be present in fine-grained material layers. Possibility of ice wedges occurrence.
 - Northern foundations on adjustable post and pad or on piles. Buildings with slab-on-grade foundations might need elaborated techniques to retain permafrost in its frozen state (ex.: thermosyphons).
- THAW-UNSTABLE GROUND: ICE-RICH PERMAFROST IN SUPERFICIAL DEPOSITS**
- 2a**
- Thin cover of heterogeneous deposit (till) over bedrock. Composed mainly of sand and silt with some gravel and boulders. The thickness of the deposit is generally less than 2 m and the topography is controlled by bedrock. Presence of scattered rock outcrops. The active layer thickness is generally ranging from 2.5 to 3 m. Contains pore ice and ice lenses in fine-grained material layers. The volumetric ice content is generally less than 30%. Occurrence of mudboils and gelifluction lobes on slopes. Creep and differential settlements may occur upon thawing, but are limited due to the shallow thickness of the deposit.
 - Deep northern foundations on the underlying bedrock applicable (ex.: Pile foundations). Adjustable post and pad foundations also feasible. Buildings with slab-on-grade foundations need elaborated techniques of terrain preparation (ex.: removal or pre-thaw of frozen sediments and consolidation).
- 2b**
- Thick cover of heterogeneous deposit (till) over bedrock. Composed mainly of sand and silt with some gravel and boulders. The thickness of the deposit is generally more than 2 m with occasional bedrock outcrop. The active layer thickness is generally ranging from 2.5 to 3 m. Contains pore ice and ice lenses in fine-grained material layers. The volumetric ice content is generally less than 30%. Occurrence of mudboils and gelifluction lobes on slopes. Creep and differential settlements may occur upon thawing.
 - Pile foundations feasible but require deeper drill-holes for pile driving. Adjustable post and pad foundations also feasible. Buildings with slab-on-grade foundations need elaborated techniques to retain permafrost in its frozen state (ex.: thermosyphons). Steeper slope sections may be affected by gelifluction and may require
- 2c**
- Fine-grained deposit of marine origin (sand, silt and clay) sometimes covered with a thin layer of organic, alluvial or littoral sediments. Poorly drained. The active layer thickness is ranging from 0.5 to 1.5 m. Contains ice lenses. The volumetric ice content regularly exceeds 30% and may reach almost 100%. Possibility of ice wedges occurrence. Material subject to significant differential settlements and failure on slopes upon thawing.
 - Adjustable post and pad foundations. Buildings with slab-on-grade foundations need elaborated techniques to retain permafrost in its frozen state (ex.: thermosyphons). Excavation shall be avoided.
- SEVERE LIMITATIONS: DYNAMIC ACTIVE PERIGLACIAL AND SLOPE PROCESSES, LITTORAL ZONE OR FLOODPLAINS**
- 3**
- Contemporary deposit affected by current and dynamic geomorphological processes. Subjects to erosion, flooding and slope movements.
 - Problematic terrains to be avoided.
- LEGEND**
- QUARRY (active or inactive)
 - SAND OR GRAVEL PIT (active or inactive)
 - BUILDING
 - TRANSPORT INFRASTRUCTURE
 - GEOLOGICAL UNIT BOUNDARY
 - FROST CRACK (possibility of ice wedge occurrence)
 - WATERCOURSE - creek or stream
 - ISOLATED ROCK OUTCROP
 - PERMAFROST WITH RECOVERY
